Taxonomy

Kingdom	Phylum	Class	Order	Family
Animalia	Chordata	Chondrichthyes	Carcharhiniformes	Carcharhinidae

Scientific Name: *Scoliodon laticaudus* Müller & Henle, 1838

Synonym(s):

- *Carcharias muelleri* Valenciennes, 1839
- *Carcharias palasorra* Bleeker, 1853

Common Name(s):

- English: Spadenose Shark
- Arabic: ماسح شرق

Taxonomic Source(s):

Fricke, R., Eschmeyer, W.N. and Van der Laan, R. (eds). 2020. Eschmeyer's Catalog of Fishes: genera, species, references. Updated 03 February 2020. Available at: <http://researcharchive.calacademy.org/research/ichthyology/catalog/fishcatmain.asp>.

Taxonomic Notes:

The genus *Scoliodon*, represented by *S. laticaudus*, was previously considered monotypic but now consists of three species with *S. macrorhynchus* resurrected from the junior synonym of *S. laticaudus* (White et al. 2010).

Assessment Information

Red List Category & Criteria: Near Threatened A2d [ver 3.1](#)

Year Published: 2021

Date Assessed: April 29, 2020

Justification:

The Spadenose Shark (*Scoliodon laticaudus*) is a small (to 91 cm total length) shark that occurs in the northern Indian Ocean from the Gulf of Oman to Myanmar. It is common in coastal and estuarine waters at depths of 10-75 m, but more typically less than 50 m and prefers muddy and sandy substrates and often occurs near large freshwater outflows. It is highly productive with annual large litters of 6–20 pups, early maturation at two years and a short generation length of 4.5 years. The species is caught mainly by trawl and gillnet in industrial and artisanal fisheries and is retained for human consumption. It is the dominant shark landed in Pakistan, northern India, and Bangladesh and fishing pressure is intense

across most of its range. The high productivity of the species and short generation length likely provide it with resilience to fishing pressure, however, the intense and ongoing fishing pressure on this species is a cause for concern. It is suspected that the Spadenose Shark has undergone a population reduction of 20–29% over the past three generation lengths (14 years) and is close to reaching the population reduction threshold due to levels of exploitation, and it is assessed as Near Threatened (nearly meeting Vulnerable A2d).

Geographic Range

Range Description:

The Spadenose Shark occurs in the Eastern and Western Indian Oceans, from the Gulf of Oman to Myanmar and possibly to Thailand (Ebert *et al.* 2013, Krajangdara 2019). Its status in the Arabian/Persian Gulf is unclear with historic records having suggested its presence (Wright *et al.* 1990) but extensive recent market and fishery surveys have failed to identify it (Moore *et al.* 2012, Jabado *et al.* 2015a). This species is not present in Sri Lanka (D. Fernando unpubl. data 2020). Records from Tanzanian, Kenya, and Somalia are likely to be misidentifications and this species does not appear in local guidebooks (A.J.L. Temple pers. comm. 9/11/2020).

Country Occurrence:

Native, Extant (resident): Bangladesh; India; Iran, Islamic Republic of; Myanmar (Myanmar (mainland)); Pakistan

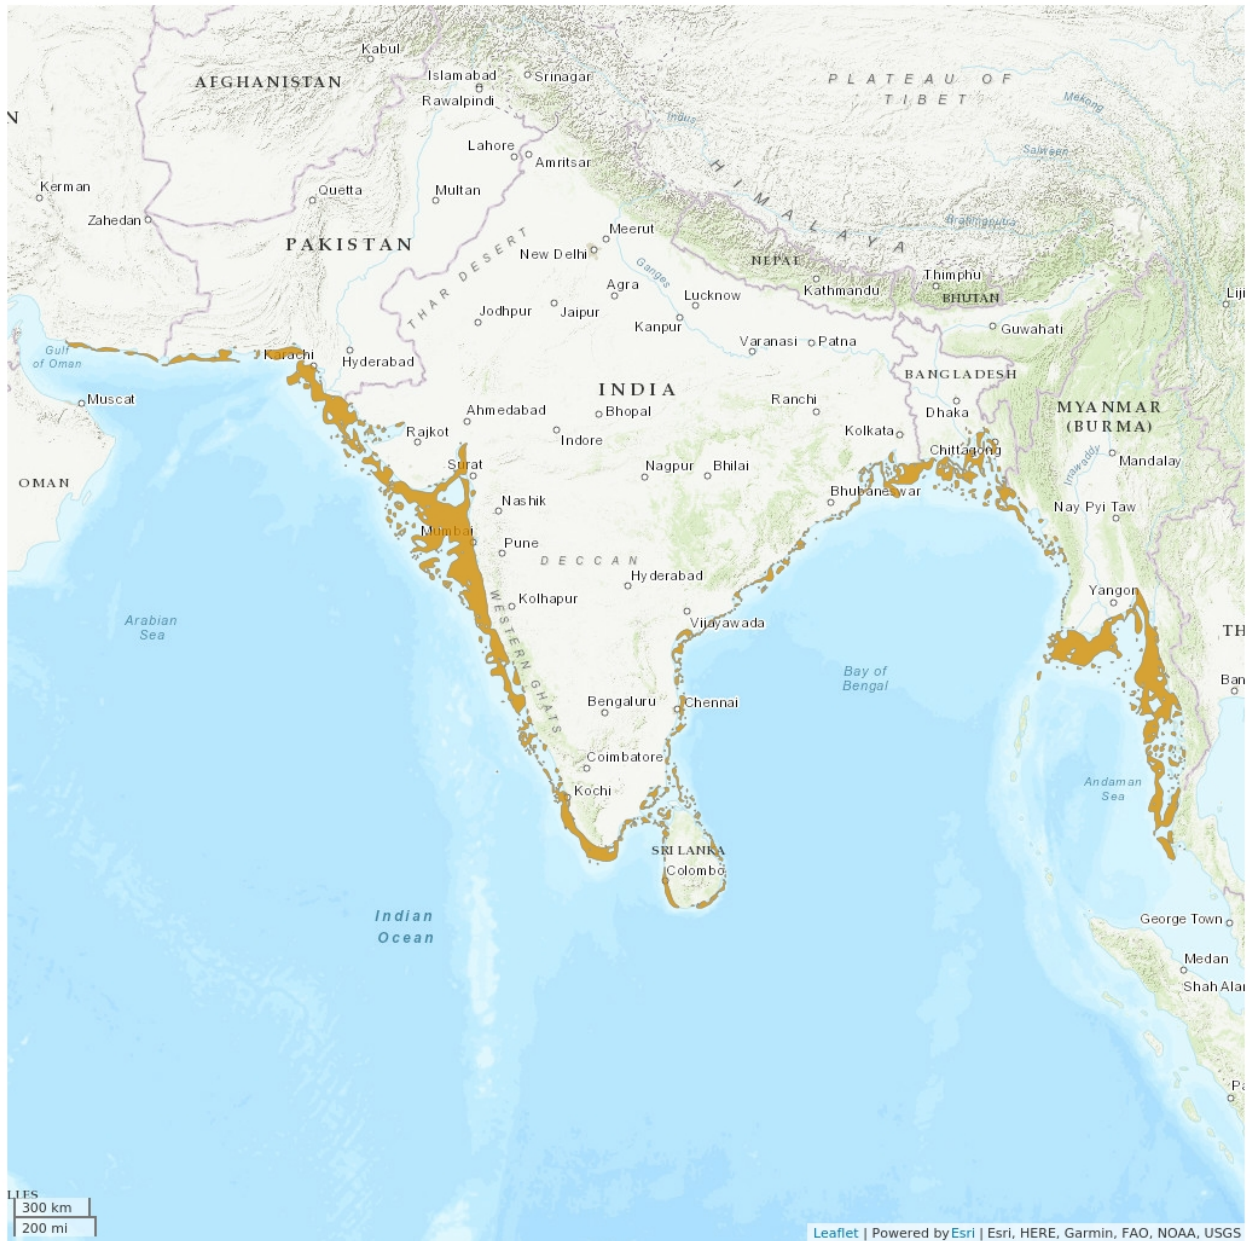

Native, Possibly Extant: Sri Lanka; Thailand

FAO Marine Fishing Areas:

Native: Indian Ocean - eastern

Native: Indian Ocean - western

Distribution Map

The boundaries and names shown and the designations used on this map do not imply any official endorsement, acceptance or opinion by IUCN.

Population

There are no species-specific population trends. Fisheries in the region have experienced increased demand for sharks since the 1970s due to the shark fin trade and as a result, effort is increasing in traditional shark fisheries in many areas (Henderson *et al.* 2007, Jabado *et al.* 2015b). Reports from India indicate that several shark stocks are either declining or have already collapsed (Mohamed and Veena 2016). While there is limited species-specific information available on this species in the region, it is marketed for consumption across its range, and the presence of intensive fisheries mean that like many other sharks in the region it has declined.

In Pakistan, it is one of the most commonly landed shark species although over the past 10 years, there has been about a ~30% decline in landings (M. Khan pers. comm. 9 February 2017, 12 December 2020). Similarly, in India, this is one of the dominant shark species caught in the northern states (Kizhakudan *et al.* 2015). This species is the dominant component of the shark catches in Gujarat, with an annual average landing of 6,364 t, and it represented 67% of shark catch during 2012–2016 (Sen *et al.* 2019). Recent catches have been stable and a length-based stock assessment suggests the exploitation ratio is around 0.53 suggesting the stock is overfished and overfishing is occurring (i.e. $E > 0.5$) (Sen *et al.* 2019). Annual catches in Maharashtra between 2010–2015 were approximately 3,131 t (G.B. Purushottama pers. comm. to K.V. Akhilesh 9 February 2017). At the Cochin Fish Harbor (Kerala state), in 1981–1982, this species represented between 4.7–8.0% of shark landings, but these landings contributed <1% in 2008 (Akhilesh *et al.* 2011). In 2003–2004, reports indicate that 11,795 t were landed along the northwest coast of India and 47 t in the southwest (Raje *et al.* 2007). Trawl data from Mumbai in Maharashtra indicate declines in landings of this species from 1,269 t in 1999 to 839 t in 2005, and it represented 66% of landed species by weight during the 1991–2005 period (Raje *et al.* 2015). When scaled to three generation lengths (14 years) of the Spadenose Shark this is equivalent to a population reduction of 85%. In Karnataka, trawlers accounted for 72% of the catch of this species and mostly operated within depths of 10–50 m (Thomas *et al.* 2020) The average catch of Spadenose Shark for the period 2012–2017, was estimated to be 112 t, which formed about 13% of the total shark landing in the region, the average catch-per-unit-effort (CPUE) was 3.4 kg (Thomas *et al.* 2020).

This species is the most frequently landed shark species in Bangladesh and comprises 58% of shark landings (A.B. Haque unpubl. data 2020). This species is mainly taken as bycatch of the Hilsa Shad (*Tenulosa ilisha*) drift gillnet fishery. A length-based stock assessment suggests the exploitation ratio is around 0.57 suggesting the stock is overfished and overfishing is occurring (i.e. $E > 0.5$) (Karim *et al.* 2017). This species, or one like it, is known from Myanmar and captured with demersal trawls, gillnets and line gears (Psomadakis *et al.* 2019, A. Maung unpubl. data 2020).

Although landings data are not a direct measure of abundance, these can be used to infer population reduction where landings have decreased while fishing effort has remained stable or increased. Reconstructed catches of mainly carcharhinids are available for the western and northern Indian Ocean and Red Sea (Large Marine Ecosystems 31–34), ranging from Tanzania to Thailand (Zeller and Pauly 2016). Reconstructed catches rose rapidly since the 1960s peaking at a catch of 90,984 t in 1974. Since then catches have declined by 58 over 42 years (1974–2016), with a very steep decline in catch of 48% over 12 years (2004–2016). When scaled to three generation lengths (14 years) of the Spadenose Shark, this is equivalent to a population reduction of 54%.

The species is likely to be resilient enough to withstand moderate fishing mortality and there may be localised stability in catch trends. With increasing fishing pressure across the Indian Ocean region, it is suspected that this species has declined by 20–29% over the past three generation lengths (14 years) and is close to reaching the population reduction threshold due to levels of exploitation.

Current Population Trend: Decreasing

Habitat and Ecology (see Appendix for additional information)

The Spadenose Shark is demersal in coastal and estuarine waters at depths of 10–75 m, but mostly less than 50 m (Weigmann 2016, Sen *et al.* 2019, R.W. Jabado unpubl. data 2020). The species prefers muddy and sandy substrates and often occurs near large freshwater outflows. It reaches a maximum size of 91 cm total length (TL), males mature at 24–36 cm TL and females mature at 33–35 cm TL (Ebert *et al.* 2013, Weigmann 2016, Sen *et al.* 2018, R.W. Jabado unpubl. data 2020). Breeding occurs throughout the year (Devadoss 1979) and females probably mate at least once each year. Reproduction is placental viviparity, with potentially the most significant placental investment in offspring of all elasmobranchs (Wourms 1993). Litter sizes are 6–20, with a mean of 13 (Devadoss 1979) and young are born throughout the year after a gestation period of 5–6 months with a size-at-birth of 12–15 cm TL (Ebert *et al.* 2013). Female age-at-maturity is around two years and maximum age is seven years; generation length is therefore 4.5 years (Nair 1976).

Systems: Marine

Use and Trade

The meat of this species is often sold fresh for human consumption at local markets across the region. In Pakistan and India, the meat is cut into fillets, dried, and salted for domestic sales or trade with neighbouring countries. Fins are not considered valuable due to their small size but are still traded internationally (Jabado *et al.* 2015b, Cardeñosa *et al.* 2020).

Threats (see Appendix for additional information)

This species is commonly taken in fisheries throughout the Indian Ocean. This includes coastal set gillnet fisheries for a wide range of fish including bony fish and sharks. It is also caught incidentally in demersal trawls for shrimp and fish. In some parts of the region, it is also commonly taken in handline fisheries. Fisheries that catch this species are often small-scale artisanal fisheries, although some trawl fisheries are carried out by commercial and foreign vessels. In some regions (e.g. India, Pakistan) fishing effort on this species has been increasing in recent years. For example, in India, there are over 13,400 gill netters operating along the west coast, with many other types of net gear also deployed in coastal areas (CMFRI 2010). Furthermore, there were about 6,600 trawlers operating in the Indian state of Gujarat in the early 2000s (Zynudheen *et al.* 2004). This number almost doubled to 11,582 trawlers in 2010 (CMFRI 2010). In Pakistan waters, about 2,000 trawlers operate in shelf waters, targeting shrimp in shallow waters and fish in deeper shelf waters (M. Moazzam Khan pers. comm. 6 February 2017).

Conservation Actions (see Appendix for additional information)

There are no species-specific conservation measures in place. India and Pakistan have seasonal trawl bans that might benefit the species, however, incidental catches occur in other fisheries (e.g., gillnetting). In India, coastal waters up to 9 km from shore and five to ten fathom depth (at specified

areas) are restricted for mechanised fishing in Indian coastal states Gujarat and Maharashtra, where the Spadenose Shark is caught in large quantity (K.V. Akhilesh unpubl. data 2020). Further research is needed on population size and trend, and life history, and catch rates should be monitored.
