## COMMERCIAL TRAWL FISHERIES

## Introduction

Experimental and exploratory trawling off Kakinada by the Central and State Government organisations was initiated in 1960 but the commercial exploitation of the resources by small-sized trawlers started in 1964. Since then, the industry expanded substantially by increasing both the size and number of the trawlers. The staff attached to the Research Centre at Kakinada have been collecting data in a systematic way on various resources, since the beginning of commercial trawling at Kakinada, to understand the resource characteristics and also to provide the data to various organisations and enterpreneurs interested in the same. The data collected during the 10 year period (1969-1978) are incorporated in this report.

Presently the fishing is conducted in the sea off Kakinada between $16^{\circ} 35^{\prime} \mathrm{N}-17^{\circ} 25^{\prime} \mathrm{N}$ latitude and $82^{\prime} 20^{\prime} \mathrm{E}-83^{\circ} 10^{\prime} \mathrm{E}$ longitude (fig. 1) at depths ranging from 5 to 80 m . During the earlier years however,

Fig. I. Map of fishing ground.
the area covered was less (vide:Muthu et al., Indian J. Fish., 22: 1975.) The boats conduct daily fishing during day time and land the catches by evening but during certain months (November-February) some boats conduct night fishing also and land the catches in the early morning.

## Craft and Gear

Three types of boats are engaged in fishing in the region. The particulars of the sizes of the boats, engine and the nets used are given in Table 1. The commercial fishery started with small boats (Pablos) and subsequently boats of two more sizes were added to the fleet (Table 1) but there was considerable increase in the Pomfret and Royya boats over the years, whereas similar increase was not noticed for Pablos and Sorrahs (fig. 2).

## Fisheries

Data on the catches collected over a period of ten years from 1969 to 1978 (Table 2) show that on an average 6,691 tonnes of fish including 1,666 tonnes of

Fig. 2. Details of types of boats operated in different years and estimated total catches.
prawns are landed at this centre annually. There are differences in the seasonal variations of the ground fish abundance on the trawling grounds in different years

[^0]Table 1. Defails of the Craft and Gear used at Kakinada.

| Type of | Particulars of the vessels |  |  |  | Particulars of the gear operated |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Length m | Beam m | Draft m | Engine HP | Type of net | Length of Head rope | Mesh size <br> cm | Otter boards | Rigging | Net operation |
| Pablo | 9.14 | 2.49 | 0.87-0.97 | 20-30 | 2-seam cotton trawi during earlier years 2-seam and 4-seam trawlmade of synthetic monofilament of $0.5-1.0 \mathrm{~mm}$ diameter. | $\begin{aligned} & 11.89 \& \\ & 12.95 \mathrm{~m} \end{aligned}$ | Wings: 7.6 Body: 3.8-5.1 codend 0.8-2.5 | Shape: <br> oval <br> during early periods Flat Rectangular now. Wt: 35 kg . | Double expanded legs upto a length of $5-10 \mathrm{~m}$ | Mechanical winch with G.I. wire rope. |
| Pomfret \& Royya | $\begin{aligned} & 9.75 \& \\ & 10.0 \end{aligned}$ | 2.9 | 1.07 | 45-60 | -do- | 14.94, 16.5 and 18.29 m In some cases the wings are extended even up to 27.44 m to cover wider | area. | $\begin{aligned} & \text { Wt: } \\ & 40-45 \mathrm{~kg} . \end{aligned}$ | ```-do- with a length of 15-20m.``` | -do- |
| Sorrah | 11.41 | 3.2 | 1.22 | 60-75 | -do- | -do- | -do- | $\begin{aligned} & \text { Wt: } \\ & 45-60 \mathrm{~kg} . \end{aligned}$ | -dowith a length of $10-20 \mathrm{~m}$. | -do- |

but a peak in January-March period is more or less common to all years (Table 3). Several species contribute to the fishery and the data are collected by separating the catches into 33 groups as given in Table 2. Of these, prawns, sciaenids, ribbon fish, silver bellys, Decapterus sp, Nemipterus spp, Psenes sp, Lizard fish, Bombay Duck and flat fish are the dominant items (in the order of abundance) in the catches. The seasonal variations in the catches of these ten groups for the period 1969-78 (averages) are presented in Table 4.

## Prawns

Prawns form the most dominant component in the trawl catches accounting for about $25 \%$ of the total catches (Table 2). 30 species of penaeid prawns and 7 species of non-penaeid prawns contribute to the fishery. Important species of penaeid prawns in the order of abundance are: Metapenaeus dobsoni, M. monoceros, M. affinis, Penaeus indicus, P. monodon, Parapenaeopsis stylifera, Solenocera crassicornis, $P$. hardwickii and $P$. merguiensis. Among non-penaeid species, Acetes spp, Exopalaemon styliferus, Nematopalaemon tenuipes and Exhippolysmata ensirostris are important. The details regarding the prawn fisheries at Kakinada during the study period have been reported by Sudhakara Rao et al. (Mar. Fish. Infor. Serv. $T \& E$ Ser., No. 21, 1980).

## Sciaenids

These fishes occupy second position in regard to abundance. The catches showed an increasing trend till 1972; in 1973 there was a decline but considerable increase was seen from 1974 to 1977; in 1978 again there was a decline to the tune at $86 \%$ with only $18.6 \%$ decrease in the effort when compared to 1977. There are two peaks in the seasonal abundance, one in AprilMay and the other in August-September. About 17 species contribute to the fishery with Johnius carutta, J. dussumieri, J. vogleri, Pemmahia macrophthalmus, Atrobucca nibe and Otolithus ruber dominant.

## Ribbon fish

An estimated annual average catch of 536 tonnes were obtained by the trawlers during the tenyear period. Starting from 1969, the catches showed gradual increase in the next two years but in 1972 there was decline. The catches however increased in 1973 and this increasing trend continued till 1977 but in 1978 there was a decline. Though ribbon fish is a pelagic resource, they are caught in considerable quantities by the trawlers when these fishes move into the trawling ground in large shoals. The data show that these fishes are abundant on the fishing ground during April-June. About 6 species occur in the catches but

Table 2. Estimated catches (kg) of different groups/species by three types of boats combined during different years.

| SI. No. | Name of fish | 1969 | 1970 | 1971 | 1972 | 1973 | 1974 | 1975 | 1976 | 1977 | 1978 | $\begin{gathered} \text { Average } \\ \text { for } \\ 1969-78 \end{gathered}$ | Percentage | Rank |

Trichiurus leptures is the most dominant, contributing about $70 \%$ of ribbon fish catches.

## Silverbellys

An average of about 500 tonnes are landed annually forming about $7.5 \%$ of total landings. The catches of these fishes also showed decline during 1977 and 1978. Although contributing to the fishery throughout the year, they are most abundant during JanuaryMarch period. Out of 10 species, Leiognathus bindus and Secutor insidiator are most abundant.

## Decapterus sp.

These fishes form a seasonal fishery, most abundant during January-March. Like ribbon fish, this species also is pelagic and caught by trawls when large shoals move into the fishing ground. There are wide fluctuations, like many other pelagic resources, in the catches during different years (Table 5). An average of 391 tonnes are landed annually forming about $6 \%$ of trawl catches.

## Nemipterus spp.

The ten year average estimated catches show that about 375 tonnes of these fishes are landed annually forming $5.6 \%$ of trawl catches. The data on seasonal abundance show that January-March and OctoberDecember are the peak periods for these fishes, the first quarter, however, being more productive. Five species occur in the catches, $N$. japonicus being the most dominant.

## Penses sp.

This species occurs seasonally and about $90 \%$ of the annual catch comes during January-March period. There are wide fluctuations in the catches in different years (Table 5). An average of 320 tonnes are landed annually forming $4.8 \%$ of the catches.

## Lizard fish

The annual estimated catches range from a minimum of 16 tonnes in 1969 to a maximum of 711 tonnes in
1977. From 1969 the catches showed increase till 1972 but in 1973 there was a deep decline. There was improvement from 1974 till 1977, again declining in 1978. These fishes occur in large quantities during January-March period. About 3 species occur, of which Saurida tumbil is the most dominant.

## Bombay Dack

Harpodon nehereus occurs seasonally in large quantities. The ten-year data show that this species is abundant during July-September period. The catches showed increasing trend in successive years. Starting with less than 1 tonne in 1969, an estimated 865 tonnes were landed in 1978, the ten year average being 180 tonnes forming $2.7 \%$ of the trawl catches.

## Flat fish

The estimated annual average catch of these fishes is 185 tonnes forming about $3 \%$ of total catches. Psettodes erumei and Cynoglossus spp are the important species. These fishes occur almost round the year but they are most abundant during JanuaryMarch period.

## Remarks

In general there was deep decline in the catch per unit effort during 1973 and 1978 for the total trawl catches (Table 2). It is however, observed that the catches showed steady increase from 1969 to 1977 without decline in 1973 and declined only in 1978. So the decline in catch rate in 1973 appears to be brought about by the heavy input of effort, almost double that of the previous year. But in 1978 there is decline in total catch, effort and catch rate.

As already pointed out by Silas et al., (Bull. Cent. mar. Fish. Res. Inst., 27, 1976) and Sudhakara Rao et al (Mar. Fish. Infor. Serv. $T \& E$ Ser., 21, 1980), trawling is almost exclusively carried out for prawns because of the export market. This has resulted in extensive coverage of certain parts of the fishing grounds and little or no coverage of other parts, thus affecting the production of other demersal resources. In this connection it may be pointed out that Sriramachandra Murty (Ms: A study of the Sciaenid fisheries off Kakinada along the east coast of India) observed that
increase in effort in different years did not bring increased sciaenid catches. Further it has also been shown that in some years, periods of peak effort coincided with periods of poor catches of sciaenid fishes. This increased effort was apparently used to catch prawns in certain parts of the fishing ground. In fact the demand for prawns has also lead to the reduction of the cod end mesh size of the trawl nets (Sudhakara Rao et al., Mar. Fish. Infor. Serv. T \& E Ser., 21, 1980) in recent years. Though this has resulted in the increase of the small-sized non-penaeid prawn catch, there is no recognisable change in the length composition of the important groups of finfish caught. This again, is probably, due to the uneven distribution of effort on the fishing ground with the sole aim of catching more prawns. It may be pointed out here that majority of the boats conduct trawling in the inshore waters of $5-20 \mathrm{~m}$ depth zone where it is known that the prawns are abundant. If the effort is uniformly distributed on the fishing grounds one would expect large quantities of early juveniles of fish also to be caught at least during certain seasons, on account of reduction in the cod end mesh size.

The boats carry ice in boxes to bring prawns but no such arrangement exists for bringing fin fishes though they constitute about $70 \%$ of the catches. This is because the deck-space is not sufficient to keep more boxes with ice and also there is lesser demand for them as compared to prawns. A consequence of this is that in majority of the cases, most of the fishes are spoiled by the time they are landed and hence are not fit for consumption in fresh condition. These fishes are sold at very cheap prices for purposes of saltcuring and sun-drying.

Since the boats are small (Table 1) and have to return to the base every day, the scope for further expansion of the fishing ground is limited. In the light of these observations it is felt that uniform distribution of effort on the existing fishing ground would help increase production of important fin fishes. This, however has to be done keeping the prawn production in view. Another approach would be to introduce larger vessels that can venture into deeper areas which are not covered so far. In any case constant monitoring of the resources would be essential in order to enable appraisal of the fisheries with proper management approach.
